
WILD EDIBLE PLANTS AND THEIR TRADITIONAL USE IN THE HUMAN NUTRITION IN BOSNIA-HERZEGOVINA

SULE JMAN REDZIC

Center of Ecology and Natural Resources, University of Sarajevo, Department of Botany, Sarajevo, Bosnia, Herzegovina

This article presents first systematical procedure results on traditional usage of wild, edible, vitaminous, and aromatic plants in the nutrition of human population in Bosnia and Herzegovina (W. Balkan peninsula; SE Europe). By method of an ethnobotanical interview, which comprised of over 250 persons, whose average age was 55, and by research on edible wild flora all around Bosnia and Herzegovina that extended over many years, detected were 308 plants belonging to 73 plant families that are being used in nutrition and diet of indigenous population. Edible wild plants are used as delicious vegetables, fruits, peer and spices, in either fresh, raw, or dried condition. Plants are being used for the making of cooked food (33%), fresh salads (19%), mush and bread (17%), or as fresh, wild fruits and drinks (13%) or as spices and ethno-pharmacological potions (10%). The majority of identified, wild edible plants may satisfy the daily human need for elementary nutrition material, particularly those of vitamins C and A, and for some minerals, according to the regulations of World Health Organization (WHO).

KEYWORDS nutrition, wild food, human ecology, ethnobotany, biodiversity, Balkan peninsula

INTRODUCTION

One of the most important problems of the current era is hunger. Despite the fact of stepping into the 21st century, according to World Health Organizations (WHO's) estimation, more than one-third of human population suffers from hunger or severe malnutrition, one-third goes to bed semi-hungry or hungry, while only one-third of the world population fully enjoys all the benefits of adequate food supply (ACC/SCN, 1992–1993).

On the other hand, there has been an increasing trend of food contamination by various kind of toxic compounds (pesticides, fertilizers, all sorts of pollutants from the environment), which is prevalent most factor that influences human health. This kind of food additives cause a wide spectrum of pathological conditions in the human body, including different forms of cancer (WHO, 1995). It would be impossible to exclude these food from the human diet entirely due to an increase in hunger all additives over the world. However, certain preventive measures and steps can be undertaken in order to improve the current situation as much as possible.

Hence, there are two major problems facing mankind when it comes to the human diet: First, how to discover potential food resources and decrease hunger that becomes more prevalent everyday, and second how to provide sources of healthy food that would be acceptable for humans. One part of the solution should be looked for in the bio-technology and new technological discoveries. It is commonly believed that this dilemma will be successfully solved in future and that hunger will be minimized in general, or at least evenly distributed on the planet. But in these modern days, there are hungry people who require only minimal assistance to be sufficiently supplied with food, while the rest of the population urgently needs a larger amount of healthy and ecologically safe food.

Wilderness in many parts of the world rich in self-grown vitaminous and spicy plant species that could be a solid base for solving these problems. Although these resources are not an adequate basis for human diet, they could be an important source of supplementary food for starving populations and a dietary replacement for populations that in their daily diet consume unhealthy food (Colic 1962; Becker, 1983; Agrahar-Murugkar and Subbulakshmi, 2005; Addis et al., 2005).

Usage of self-grown plants in human diet has been present since the early age of mans existence (Moffett, 1991; Kubiak-Martens, 1999). That kind of practice has continued up to modern age, especially in countries

that have been struck by chronic hunger or periodical hunger cycles (Vracaric, 1977; Sena et al., 1998; Hanazaki et al., 2000; Ladio, 2000; Lockett and Grivetti, 2000; Britta et al., 2003; Kristensen and Balslev, 2003; Tabuti et al., 2004; Glew et al., 2005).

Besides, usage of plants belonging to the wild flora, is common today as a supplement for healthy diet, even in the most developed regions of the world. Thus *Nasturtium officinale* is a necessary ingredient of salads in Scandinavian dishes and *Valerianella locusta* and *Asparagus officinale* are irreplaceable vegetables in Mediterranean countries (Grlie, 1952; 1954; Bonet and Valles, 2002; Guarerra, 2003). Wild fruits of the following species: *Fragaria vesca*, *Rubus ideaeus*, *R. fruticosus*, *R. hirtus*, *R. caesius*, *R. dalmatinus*, *Vaccinium myrtillus*, *V. vitis-idaea*, *Cornus mas*, *Sorbus torminalis*, and *S. aucuparia* are highly valued in many developed countries (Fleischhauer, 2003; Sanghvi, 2004).

The problem of nutrition and a supply of sufficient food quantities has been present in the regions of Bosnia and Herzegovina and the entire Balkan Peninsula over the past centuries, especially in the western parts. Since the beginning of human settlement on the Balkan Peninsula, which goes back to the early neolith era, man has been fighting for his survival (Fukarek, 1954; Kusan, 1956; Josifovic, 1989). This area was often stricken by crises that were followed by a lack of food over the past historical eras. People were starving not only during dry seasons of the years, but also during the wars or similar disasters, despite the fact that there was a very rich wild flora and fauna surrounding them. Wild flora and fauna were not utilized fully in human nutrition, which was brought about by widespread beliefs and prejudices. Especially in some parts of Bosnia, the following organisms were seldom used in human diet: snakes, snails, frogs, and wild vegetables. Inland people were very conservative in this point-of-view, while inhabitants of the coastline have cherished customs to use both flora and fauna in their daily nutrition since early ages. This can be explained by a small yield of cultivated plants due to common drought during the vegetative season, and progressive land erosion. Thus, inhabitants of coastline and southern Herzegovina were pushed to eat "everything that was green" in order to survive and maintain a basic existence (Bakic and Skare-Kavric, 1967; Bakota, 1967).

In other areas during the years of hunger, people preferred to eat cord (leather pieces from their shoes) or beech's bark, rather than wild fauna or delicious wild vegetables. Flowering plants were not even considered (Filipovic, 1953).

Despite a lack of education in possible sources of food that are to be found in nature, the population of this part of the Balkan Peninsula in its quite long history has developed and cherished the knowledge of nutrition with the dominance of wild edible vitaminous and aromatic plants over a particular year's seasons. Even today in some parts of Herzegovina, such as the Mediterranean Mountains, during the period of cold and strong winds, fundamental fruits for the local population are fruits of wild plants: *Crataegus monogyna*, *Cornus mas*, *Sorbus torminalis*, *Prunus avium*, especially for the children. When the richness of local flora and fauna, as well as possibility of its usage in both daily life and extraordinary situations, became obvious to humans, systematic investigation have been started in edible wild flora and fauna. One reason for this was to fulfill army requirements for development of techniques for survival in nature (Drobnjak, 1962; Ivanisevic, 1962; Colic, 1967; Rajsic, 1974; Vracaric et al., 1966, 1967; Vracaric, 1977; Grlic, 1980). These investigations have continued in cooperation with several scientific and research institutions, as well as with some groups interested in the application of surviving activities in nature.

Wild edible flora did not play a major role in the population's survival only in ancient days. It was crucial in maintenance of lives during the recent war in Bosnia and Herzegovina, especially in the cities that were under siege. At that point, in order to secure the survival of citizens by usage of wild flora in their diet, the Civil Protection Center, requested experts in this field to conduct a study that would enlighten possibilities of human survival in the situation of great shortages of food (Redzic, 1993).

There has been an increasing need for an intensive study on potential sources of healthy food contained in wild flora and fauna due to the growing problem of food shortages and the survival of humans under different conditions. Diversity of flora and fauna in some areas of the world has particular value. One of these is the area of Bosnia and Herzegovina, Mediterranean mountainous country in the central part of the Balkan Peninsula. This is the one of the richest country's in Europe when it comes to the diversity of wild flora (Redzic et al., 2003). Its natural resources have to be studied and made available local community.

The aims of this article are:

- inventarization and documentation of wild edible plants usage by Bosnian communities;

- assessment of the wild edible plants usages;
- assessment of the most common species used in Bosnia and Herzegovina;
- collecting of data on ways of meal's preparation;
- contemplating of nutrition values and comparative analyses of nutrition characteristics with plants from other areas, and evaluation possibilities of disposable species of wild plants in new forms of nutrition of contemporary man.

MATERIAL AND METHODS

Study Area

Bosnia and Herzegovina (B&H) are located in the northwestern part of the Balkan Peninsula with a total land area of 51,129 km² and some 4,600,000 inhabitants (Redzic et al., 2003). The total length of the land boundaries is 1,459 km, and that of the coastline is 20 km (Figure 1). This is mainly a hilly mountainous region. Only 5% of the total country area belongs to plains, 24% to hills, 42% to mountains, and 29% to

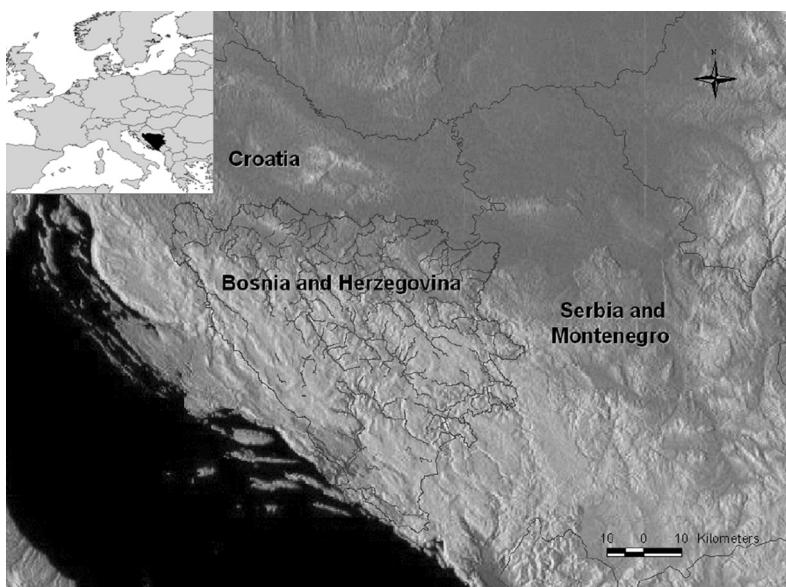

Figure 1. Geographical position of investigated area.

karst. Karst fields comprise up to 19% of the karstic area. Mean altitude above sea level is cca. 500 m (from the sea level in Neum-Klek to the Mt Maglic top 2,387 m).

The climate is very heterogeneous: Mediterranean, sub-Mediterranean, temperate continental, continental, and mountainous climate. A hydrologic network exists in numerous rivers belonging to the Black Sea basin (Una, Vrbas, Bosna, and Drina) and rivers belonging to the Adriatic Sea basin (Neretva, Trebizat, and Trebisnica).

From a phytogeographical standpoint, this area belongs to three regions: Mediterranean with Adriatic province, Eurosiberian-Boreoamerican with Illyrian province, Moesian province, and the province of relic pine forests. The highest peaks belong to the Alpine-high nordic region with more than 50% of the high Dinaric province covered with natural forests. The rest is covered with meadows, rocky grassland, and arable land. From an ecological standpoint, the largest part of the territory is still clean and acceptable, and therefore it is suitable for utilization of plant resources from their natural habitats for nutrition and healing.

Field Work

The basic method used for gathering of data was an ethnobotanical/ethnonutritional interview. The interview contained the following data:

- name and age of interviewed person
- area/region
- time of interview
- local name(s) of herbs
- part of the plant that was being used
- mode of preparation of nutritive potion
- purpose of usage
- place of growing
- Other important remarks (e.g., evaluation of conservatory status).

More than 250 adults were interviewed, average age 55, who have used wild plants in their diet under varied circumstances. Interviewed persons were members of different ethnical groups. Almost 60% were Bosnian Muslims, 39% were Bosnian Catholics and Orthodoxs, and several Hebrews and other ethnic and minority groups were also interviewed. Approximately 65% were women and 45% were men.

During every field visit, all persons that spent time in nature in any way, were interviewed if they use or are knowledgeable in the usage of wild flora with dietary purposes (mountaineers, collectors of medicinal herbs, nomads, nomad populations). On several occasions, collected herb material was displayed to the locals (in villages, suburban areas of cities, mountain lodges, mountain camps) and for those plants that were identified by them, information on its usage were recorded. Each plant that was presented to the interviewees by the investigator and recognized as having dietary purposes, was collected, photographed, and stored within the herbaria.

Intensive field explorations were done in three seasons: spring, summer, and early autumn of 2000–2004.

An enormous amount of very useful information on usage of wild flora in nutrition, both under normal and extraordinary circumstances, were collected by the author during training on survival in nature, in which the author took part (Redzic, 1993), and during the mapping of flora and vegetation (Redzic et al., 1984, 1985, 1986). Data on nutrition values of many autonomous edible plants were extracted from the literature (Vracaric, 1977; Grlic, 1980; Redzic, 1993).

All plant material has been placed within the herbaria and stored in the herbaria of medical and edible plants in the Center of Ecology and Natural Resources at the Faculty of Science, Sarajevo University (CEPRES HERB) and in the herbaria of the National Museum of B&H (SARA). A herbaria number, was assigned to each identified plant species.

Laboratory Work

Determination of plant material has been carried out by the author and final determination of some questionable data has been carried out on behalf of determined herbaria specimens from SARA and CEPRES HERB, and relevant literature (Hayek, 1927–33; Beck-Mannagetta and Maly, 1950; Beck-Mannagetta et al., 1967, 1974, 1983) Nomenclature of the plant species and their systematical belonging was determined according to the Flora Europaea (Tutin et al., 1964–1980). Preparatory procedures and fields of usage were categorized according to the following authors: Vracaric, (1977); Grlic (1980); Josifovic (1989); and Redzic (1993).

Data Analyses

These investigations have been carried out in order to gather data on:

- number of edible and some aromatic plants used in traditional nutrition,
- local plant name(s),
- number of plant families and the most frequent families,
- the most frequent plant species used in nutrition,
- types of habitats and plant communities where species lives,
- parts of plants being used,
- classification of edible plants,
- forms and presence of preparations.

RESULTS

General Data on Edible Plants

During these investigations, it has been determined that 308 vascular plant species of wild flora have had significant importance in traditional nutrition and ethnoecology in B&H. An overview on these plants and their basic data were given in Table 1. The most frequently used plants in the entire B&H region are: *Urtica dioica*, *Fagus sylvatica*, *Epilobium angustifolium*, *Chenopodium bonus-henricus*, *Brassica* sp., *Castanea sativa*, *Alchemilla* sp., *Allium ursinum*, *Beta* sp., *Atriplex* sp., *Rubus* sp., *Fragaria* sp., *Sorbus* sp., *Malva* sp., *Melissa officinalis*, *Mentha* sp., *Oxalis acetosella*, *Plantago* sp., *Polygonum bistorta*, *Rumex acetosa*, *Portulaca oleracea*, *Polypodium vulgare*, *Pteridium aquilinum*, *Quercus* sp., *Rosa* sp., *Sambucus* sp., *Sempervivum* sp., *Tussilago farfara*, *Orchis* sp., *Arbutus unedo*, *Taraxacum officinale*, *Cichorium intybus*, *Nasturtium officinale*, and others.

For the first time in the B&H region the following edible species have been recorded: *Alchemilla xanthochlora*, *Althaea rosea*, *Barbarea bosniaca*, *Geum montanum*, *G. rivale*, *Jovibarba globifera*, *Lilium cattaniae*, *Pinus heldreichii*, *Plantago reniformis*, *Silene bosniaca*, *Viola elegantula*, and others.

Identifiable edible plants belong to 74 different plant families. Most edible plants belong to the following families: *Rosaceae* (17%), *Compositae* (8%), *Labiatae* (7%), *Cruciferae* (6%), *Liliaceae* (6%), *Leguminosae* (6%), *Polygonaceae* (5%), and *Umbelliferae* (5%).

From an ecological and phytocoenological standpoint, determined plants can be categorized within 49 vegetation orders, which express

different habitat types. Most of them belong to the mesophyllous deciduous woods of the *Fagetalia* order, mesophyllous grassland of the *Arrhenatheretalia* order, anthropogenous communities of the *Chenopodietales* and *Onopordetalia* orders, then termophyllous woods and grassland of the *Quercetalia pubescens* and *Brometalia erecti* orders, as well as to sub-Mediterranean rocky grasslands of the *Scorzonero-Chrysopogonetalia* order, and to shrub's formation of the *Prunetalia spinosae* order and Mediterranean sclerophyllous, evergreen oak woods of the *Quercetalia ilicis* order.

Classification of Wild Edible Plants

In accordance with possibilities of usage, identified edible wild species are classified into four fundamental groups:

- a. vegetables
- b. fruits
- c. bread plants
- d. spices

Wild vegetables dominate this spectrum (Figure 2). Garden plants encompass tuberous vegetables with leaves and blossoms. The most common species in this group are as follows: *Urtica dioica*, *Tussilago farfara*, *Taraxacum officinale*, *Allium ursinum*, *Chenopodium bonus-henricus*,

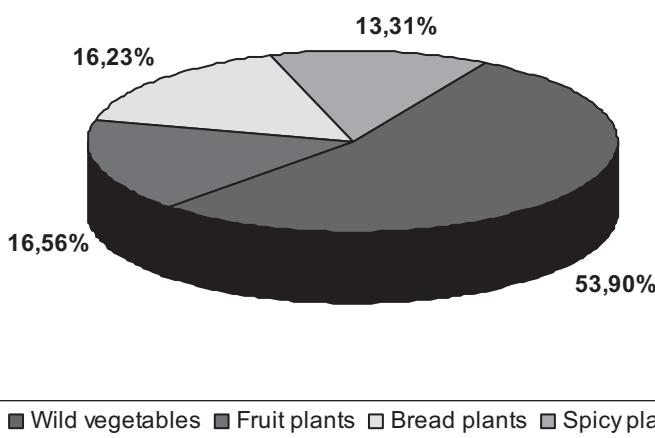

Figure 2. Classification of wild edible plants with possibilities of usage.

Amaranthus retroflexus, *Portula oleracea*, *Malva sylvestris*, *Oxalis acetosella*, *Rumex acetosa*, *Rumex patientia*, *Cichorium intybus*, *Epilobium angustifolium*, *Primula* sp., *Campanula pyramidalis*, *Crithmum maritimum*, *Nasturtium officinale*, *Alchemilla* sp., *Brassica* sp., *Pastinaca sativa*, *Picea abies*, *Polygonum bistorta*, *Pteridium aquilinum*, *Salicornia herbacea*, *Sanguisorba minor*, *Silene* sp., *Stellaria media*, and *Valerianella locusta*.

Wild fruit plants comprise 17% of the spectrum. They are widely distributed in almost every climate belt and yield fruit over the entire year. The most frequently common in this group are: *Arbutus unedo*, *Celtis australis* (mediterranean region), *Cornus mas*, *Rosa* sp., *Crataegus* sp., *Cotoneaster* sp., *Sorbus* sp., *Fragaria* sp., *Rubus* sp., *Juniperus communis*, *Malus sylvestris*, *Pyrus pyraster*, *Morus alba*, *Prunus avium*, *Prunus spinosa*, and *Vaccinium myrtillus* in other regions.

There are only a few plants where flowers are produced (approximately 16%). The most important species are: *Fagus sylvatica*, *Castanea sativa*, *Quercus* sp., *Corylus* sp., *Asphodelus albus*, *Lilium martagon*, *Orchis* sp., *Ornithogalum umbellatum*, *Phragmites australis*, *Polypodium vulgare*, *Trapa natans*, *Paliurus spina-christi*, and *Typha* sp.

The portion of spicy plants in the spectrum that have some nutritive values amounts to 13%. The most important ones are: *Laurus nobilis*, *Capparis spinosa*, *Carum carvi*, *Daucus carota*, *Geum* sp., *Hyssopus officinalis*, *Melissa officinalis*, *Origanum vulgare*, *Salvia officinalis*, *Satureja* sp., *Thymus* sp., *Viola* sp. In addition to being used as spices, a majority of these plants are being used in ethno-therapy.

Parts of Edible Plants Being Used

In the investigation, each plant's part is being used in human nutrition (root, stem, leaf, rhizoma, fruit, juices), depending on the season. The most frequently used parts are young and juicy shoots (22%), fruits (13%), overground parts such as young leaves (11%), underground parts (10%), and others as shown in Table 2

Nutritive Preparations of Wild Edible Plants

Wild edible plants in these areas are being used for making a wide array of nutritive preparations, of which the most common is cooked meals (33%), fresh salad (19%), stews and bread (17%), and fresh fruits and drinks (13%). More details are given in Table 3.

Table 2. Part of edible plants

Plant Part	Number of Species	%
Aerial part	35	11.36
Young shoots	67	21.75
Young branches/leaves	6	1.95

Sweet	2	0.65
Mush and bread (vegetables)	53	17.21
Milk fermentation	1	0.32
Total:	308	100

DISCUSSION

Usage of Edible Plants in Human Nutrition

Through detailed analysis of the results (Table 1), one can get insight into the richness of edible wild plants that have been highly significance to the human population of B&H and the Balkan Peninsula, in general, since ancient times. This is illustrated by the comparative analysis with the

results gained in a similar way for the rest of the Balkan Peninsula. Thus, there were 300 recorded vascular plants of edible wild flora in Serbia (Josifovic, 1989; Vracaric, 1977). In the Montseney Biosphere Reserve region (Catalonia, Iberian Peninsula) there were 132 edible plants identified, only 75 of them used in human nutrition (Bonet and Valles, 2002).

An ethnobotanical study on edible wild plants in a few chosen districts of Ethiopia (Addis et al., 2005) reveals 30 plants that are being used in human nutrition, especially in periods of food shortage. The same study has shown that children use edible wild plants to a much higher extent than adults. Similar experiences have been achieved in the Senegal area (Becker, 1983), where the local population uses many species of wild edible flora in its everyday nutrition.

The usage of wild edible plants is widespread in many European countries as well. For example in Italy (Guarrera, 2003), several hundred wild plants are being used in human nutrition. In the central part of Italy (Marche, Abruzzo, and Latum) 126 wild plants from 39 families are being used. In other parts of the world, such as in southeastern Asia, wild plants are highly valued as an important food source, too. Thus, investigations that were carried out by Britta et al. (2003) have confirmed that in Vietnam over 90 species of edible wild plants are being used, of which many are an unavoidable part of human medicine. Usage of wild edible plants with a nutritive purpose is especially outlined among inhabitants of South American, where several hundred species have been recorded (Ladio and Lozada, 2000a, 2000b, 2001, 2004; Hanazaki et al., 2000).

If compared with these results, Bosnia and Herzegovina are extremely rich in edible wild plants. On the other hand, this is a relatively small number when compared with the total plant diversity (about 5000 species of vascular flora) (Beck-Mannagetta et al., 1983; Hayek, 1927–1933).

Namely, a vast number of species inhabiting areas that are situated far from human settlements despite their potential nutritive value, are not being used for nutritive purposes. A similar phenomenon is evident with the usage of medical herbs (Lakusic et al., 1980, 1991; Redzic et al., 1989, 1990). These studies have shown that plants being used for their nutritive purpose indicate boundaries of human settlements, starting from sea level up to mountain peaks. The highest situated permanent settlement in B&H is on the plateau of Kupres, at 1000m above sea level, while temporary settlements such as shepherd's cottages which are active only during the summer months, during grazing season, are situated at 1600m above sea level (Vranica, Maglic, Volujak, Zelengora, Vlasic

Mountains). In mountain lodges, in everyday nutrition, healthy vegetables are prepared. *Chenopodium bonus henricus*, *Rumex alpinus*, and endemic *Plantago reniformis*, which are being prepared into very delicious and nutritive mountain soups; *Barbarea bosniaca*, numerous mountain species of genus *Alchemilla*, *Allium ursinum*, and *Allium victorialis* are prepared into healthy, delicious salads.

In their daily diet people of the coastline area use many edible wild plants, for they have less prejudices toward these food sources than the inland population. Over the entire year, thanks to the mild Mediterranean climate, it is possible to find various plants in nature that are suitable for supplementary and healthy nutrition of humans. The most important are plants growing along the shore and containing high concentrations of different ions and minerals, such as *Crithmum maritimum* and *Salicornia europaea*. Juicy parts of these plants are being used for preparation of delicious dishes and salads, along with homemade olive oil. Furthermore, soups and stews are being made with fresh plant parts from the following species: *Asparagus officinale*, *Beta maritima* (very nutritive and valued in cooking), *Brassica nigra*, and *Campanula pyramidalis*. Tasty salads are being prepared with the following: *Valerianella locusta*, *Psoralea bituminosa*, *Bellis sylvestris*, *Smilax aspera*, *Ruscus aculeatus*, and flowering buds of *Capparis spinosa*, *Salvia officinalis*, *Myrtus communis*, *Laurus nobilis* (whose leaves are added to every cooked meal) and are highly valued spices in the Mediterranean kitchen.

There are certain species whose underground parts are enriched with starch and thanks to these are being used to prepare stews and bread. Such species are: *Ornithogalum umbellatum*, *Asphodelus albus*, *A. microcarpus*, *Asphodeline lutea*, and fruits of *Palliurus aculeatus* and *Quercus ilex*. Widely distributed in the nutrition of coastline populations are also fruits of *Arbutus unedo*, *Punica granatum*, *Ficus carica*, *Celtis australis*, and *Opuntia fixus-indica*.

Plains makes up to 20% of the state's total and are situated at 300m above sea level. They encompass plains, arable areas, natural oak woods, lowland meadows, and swampy habitat types. In contrast to the other areas, here growp a majority of wild plants that contain huge quantities of carbohydrates, and due to this have been used in processing flour since ages ago. Underground organs (rhizoms) of the following plants—*Acorus calamus*, *Butomus umbellatus*, *Glychyriza glabra*, *Leucojum sp.*, *Cyperus rotundus*, *Nuphar lutea*, *Nymphaea alba*, *Phragmites australis*, and *Typha sp.*—are being harvested in order to prepare bread and tasteful stews.

More than 50% of Bosnia and Herzegovina's total area is sculptured as a mountainous/hilly relief. Different habitats of oak hornbeam, beech, and mixed beech fir woods or coniferous woods hide many edible plants. Among these plants the following dominate: *Betonica officinalis*, species of genus *Campanula*, then *Cirsium oleraceum*, *Humulus lupulus*, *Heracleum* sp., *Chamaenerion angustifolium*, *Lunaria* sp., *Leucanthemum vulgare*, *Mercurialis* sp., *Pastinaca sativa*, *Pteridium aquilinum*, *Pulmonaria officinalis*, *Symphytum* sp.

Delicious and vitaminous salads are being prepared from: *Allium* sp., *Carlina acaulis*, *Leontodon autumnalis*, *Cichorium intybus*, *Nasturtium officinale*, *Oxalis acetosella*, *Polygonum* sp., *Rumex* sp., *Trifolium* sp. In forms of fruits and vitaminous drinks used are: *Amelanchier ovalis*, *Arctostaphylos uva ursi*, *Cornus mas*, *Cotoneaster* sp., *Crataegus* sp., *Fragaria* sp., *Juniperus communis*, *Pirus* sp., *Prunus* sp., *Ribes* sp., *Rosa* sp., and some species of genus *Sorbus*, *Vaccinium* sp. (Table 1).

Nutritionally, the most frequently used edible wild plants are those that grow close to the human settlements. Man has started to use these plants at first exclusively as a food source and as phytopharmacs. Since the early days of civilization people have been preparing tasty stews, soups, pies, salads, and vitaminous drinks of wild plants such as: *Althaea* sp., *Amaranthus retroflexus*, *Atriplex* sp., *Beta vulgaris*, *Brassica* sp., *Chenopodium* sp., *Plantago* sp., *Malva* sp., *Portulaca oleracea*, *Sonchus* sp., and *Urtica* sp. Many of these plants play important roles in human medicine and in folk and religious customs.

A distribution analysis of edible plants on vertical profiles of B&H lead to the conclusion that a number of these species significantly decline as one proceeds toward higher altitudes, although B&H mountains do hide the richness of potentially edible wild plants. Many among them are endemic, such as numerous species of genus *Orchis*, *Dactylorhiza*, *Viola*, *Silene*, and *Alchemilla*, which has a significant comparative advantage from the standpoint of providing new sources of healthy food.

The majority of edible plants bring forth their fruit in spring, summer, and autumn. The lowest yield is during winter, which can be long-lasting and severe in some regions. Because of this, the first growth of stinging nettle *Urtica dioica* used to bring much joy to hungry households, for it was used in preparing stews, soups, or pies. Next in the growth cycle was dandelion *Taraxacum officinale*, then *Tussilago farfara*, and other edible plants.

During winter in the largest part of B&H apical parts are being used (short branche segments) of *Abies alba*, *Picea abies*, and *Pinus* sp. in order

to obtain vitaminous potions, which was the main food source for guerrilla fighters and the occupied population. During the recent war in B&H, people of encircled cities, used hazelnut blossom in winter's season to obtain flour from it. Flour was also obtainable from the bark of beech *Fagus silvatica* and oak *Quercus petraeae*. Salads were prepared with *Nasturtium officinale* and *Veronica beccabunga* that were collected from unpolluted springs and brooks.

During the spring months, vegetables with leaves are dominant; in summer, flowers and fruits; and in autumn, underground vegetables are important sources of carbohydrates. Although each season is marked by its own edible plants, it is possible to make it through even the harshest food shortage and survive due to the natural food resources.

An analysis of the usage of edible plants within various ethnic and cultural communities has not shown significant differences among them. In the same environment, from the ecological point-of-view, people are more or less familiar with the usage of wild plants as a nutritional supplement and medicine.

Nutritional Value of Wild Plants and Possibilities of Use

Issues of food and healthy nutrition are of utmost concern in the modern world. In order to meet current nutritional needs in the world, people strive for edible wild plants and animals (Ladio, 2000; Sundriyal, 2001, 2004; Saidov, 2001). Modern civilization has spotted big chance in these food resources as a solution to declining hunger and attaining new nutritive and medical principles that will provide healthy diets (Guil Guerrero et al., 1998; VanderJagt et al., 2000; Johnson and Grivetti, 2002; Turan et al., 2003; Glew et al., 2005).

There are poor records on nutritional values of wild plants in Bosnia and Herzegovina and also on the entire Balkan Peninsula. Nevertheless, investigations that were conducted during the twentieth century (Vracaric, 1977; Grlic, 1980; Redzic et al., 1993) have confirmed extremely a high nutritive value of some wild plants, especially those with developed overground organs. Young shoots and leaves are rich in vitamin C and carotene, and due to this play an important role in human nutrition, which is of high importance in spring when there is a lack of conventional vitamin sources.

Many plants develop underground organs that store large quantities of carbohydrates, proteins, and fats, therefore being a very useful source

of flour. Beside vitamins, keratin, and minerals, fruits of many wild plants also contain large quantities of sugar and pectin.

Wild edible plants that are known to contain an abundance of vitamin C in these investigations based on data published by Vracaric (1977), Grlic (1980), and Redzic et al. (1993) can be classified in four groups:

- A. Plants that contain more than 200 mg % of vitamin C
- B. Plants that contain between 100–200 mg % of vitamin C
- C. Plants that contain from 50 to 100 mg % of vitamin C
- D. Plants that contain less than 50 mg % of vitamin C.

Group A, among many others, comprises the following species: *Juglans regia* (3000 mg %), *Rosa canina* (do 2000 mg %), *Allium victorialis*, *Primula vulgaris*, *Sanguisorba officinalis*, *Sanguisorba minor*, *Thlaspi arvense*, *Phyteuma spicatum*, *Prunus avium*, *Typha latifolia*, *Raphanus raphanistrum*, *Ribes alpinum* (1000 mg %).

Group B is comprised of: *Alchemilla vulgaris*, *Amaranthus retroflexus*, *Brassica nigra*, *Chenopodium bonus-henricus*, *Fragaria vesca*, *Galega officinalis*, *Lotus corniculatus*, *Nasturtium officinale*, *Barbarea vulgaris*, *Capparis spinosa*, *Malva silvestris*, *Medicago sativa*, *Oxalis acetosella*, *Trifolium pratense*, *Rubus idaeus*, *Rubus fruticosus*, *Silene vulgaris*, *Sorbus aucuparia*, *Valerianella locusta*, *Rumex crispus*, *Rumex patientia*, *Physalis alkekengi*, *Plantago major*, *Filipendula vulgaris*.

Group C are: *Abies alba*, *Atriplex hortensis*, *Capsella bursa pastoris*, *Foeniculum vulgare*, *Lamium purpureum*, *Lepidium draba*, *Atriplex nitens*, *Campanula trachelium*, *Chamaenerion angustifolium*, *Chenopodium album*, *Heracleum sphondylium*, *Ononis spinosa*, *Rumex acetosa*.

Group D includes the following species: *Achillea millefolium*, *Aegopodium podagraria*, *Arctium lappa*, *Cichorium intybus*, *Crithmum maritimum*, *Pastinaca sativa*, *Polygonum bistorta*, *Sedum acre*, *Symphytum officinale*, *Taraxacum officinale*, *Stellaria media*, and many others.

Usage of the aforementioned species, as well as similar wild plants from this area, may fulfill the needs of the human body for vitamin C as one of the essential substances in the development and life of modern man.

Investigations that were performed all over the world on nutritive composition of wild plants indicate a high content of proteins (Freiberger et al., 1998; Glew et al., 2005), fatty acids (Guil et al., 1996;

Guil Guerrero and Rodriguez-Garcia, 1999), then high quantities of minerals, especially K, Na, Ca, P, Mg (Guil Guerrero et al., 1998; Agrahar-Murugkar and G. Subbulakshmi, 2005). Investigations of the vitaminous composition of wild plants indicate a great amount of vitamin C, then keratin (Zennie and Ogzewalla, 1977; Guil et al., 1997), and similar compounds that indicate great anti-oxidant properties of these plants (Cook et al., 1998; Sena et al., 1998; Kelawala and Ananthanarayan, 2004). There are some of them, such as fruits of plant *Rosa canina* from several localities in Turkey that contain a wide spectrum of fatty acids: palmitic (3.17%, 1.71%, and 2.14%), stearic (2.47%, 2.14%, and 1.69%), oleic (16.73%, 18.42%, and 14.71%), linoleic (54.41%, 51.71%, and 48.64%), linolenic (17.14%, 16.42%, and 18.41%), and arachidic (2.11%, 1.87%, and 2.61%) (Ozcan, 2002).

In some cases, wild edible plants can be an efficient means to increase weight and the condition of the female body, which is important in many undeveloped countries where women suffer malnutrition in comparison to men (Salehi et al., 2005).

Many of investigated wild edible plant's species originating from the territory of B&H and the Balkan Peninsula, according to the rules of WHO (WHO, 2002) may satisfy human body needs for vitamin C and because of that be a much more efficient prevention for contagious diseases and any other pathological conditions of the human body, securing more healthy and qualitative life (WHO, 1990). Besides, cancerogenous conditions can also be prevented by the exploitatation of wild plant richness with vitamin C (Young et al., 1997). People believe that it is enough to consume 2–3 fresh leaves of certain species of genus *Primula* to satisfy the daily needs of the body with this priceless substance.

The needs of the human body for vitamin A can be satisfied mainly by the consumption of wild edible plants (FAO/WHO, 1988) in turn preventing many diseases and securing a more adequate development of children (Blomhoff, 1991; WHO, 1995, 1998). The regular usage of vitamin A may prevent the most malitious diseases, such as leukemia and similar forms of cancer (van Dillen et al., 1996).

Wild plants growing in the territory of B&H might be more than a local food resource. Thanks to its high quality and ecological safety, they could be a source of very valuable nutritive substances containing vitamins and minerals, and to become a significant base for human nutrition creating better health, development, and sustainable life in accordance with a global agenda in fighting malnutrition in the population (WHO, 2000).

Usage of Wild Edible Plants in Ethnotherapy

A significant number of wild edible plants (Table 1) are used in ethnopharmacology. Since early civilization, people have been using a majority of these plants for the treatment of various diseases. Some of them are used both in ethnopharmacology, official pharmacy, and in medicine (PH.Yug. IV, 1984).

In the treatment of different respiratory diseases, the most frequently utilized plants are: *Ajuga reptans*, *Allium ursinum*, *Betonica officinalis*, *Fraxinus ornus*, *Hyssopus officinalis*, *Laurus nobilis*, *Inula helenium*, then species of genera *Malva*, *Althaea*, *Pinus*, *Orchis*, *Plantago*, *Primula*, *Sambucus*, *Satureja*, *Thymus*, *Tilia*, *Viola*, as well as following species: *Myrtus communis*, *Pimpinella saxifraga*, *Pulmonaria officinalis*, *Salvia officinalis*, and *Tussilago farfara*. These plants were used in the making of teas, decocts, syrups, tinctures, and etheric oils, following the rules prescribed by traditional recipes (Sadikovic, 1928).

A second group is composed of edible plants that are used in the treatment of gastro-intestinal illnesses such as: *Achillea millefolium*, *Acorus calamus*, *Angelica archangelica*, *Artemisia vulgaris*, *Capsella bursa-pastoris*, *Centuarea jacea*, *Cichorium intybus*, *Carum carvi*, *Foeniculum vulgare*, *Glycyrrhiza glabra*, *Palliurus spina christi*, *Polygonum bistorta*, *Potentilla erecta*, *Sanguisorba officinalis*, *Punica granatum*, *Taraxacum officinale*, species of genus *Rosa*, *Mentha*, *Quercus*, *Rubus*, and *Rumex*, of which were used flourishing outgrowths, roots, or rhizomes, in order to prepare teas, decocts, and medical flour (Sadikovic, 1928; Ib Al Nefis, 1961).

Urinary system diseases are treated primarily with: *Arctium lappa*, *Arctostaphylos uva-ursi*, *Betula pendula*, *Calluna vulgaris*, *Carlina acaulis*, *Eryngium campestre*, *Glycyrrhiza glabra*, *Galega officinalis*, *Ononis spinosa*, *Physalis alkekengi*, *Polygonum aviculare*, *Ruscus aculeatus*, *Silene vulgaris*, *Urtica dioica*, *Vaccinium myrtillus*, and different species of genus *Bellis* and *Juniperus*. Leaves, roots, and fruits of these plants are basis for all sort of teas (Sadikovic 1928; Grujic-Vasic and Redzic, 2003).

Certain species have been used as tranquilizers for centuries: *Geum urbanum*, *Humulus lupulus*, *Hypericum perforatum*, *Mentha pulegium*, *Artemisia vulgaris*, *Thymus serpyllum*, and *Viola odorata*. Heart and vein diseases have been treated with: *Asperula odorata*, *Filipendula ulmaria*, *Melilotus officinalis*, *Nasturtium officinale*, *Marrubium vulgare*, different species of genus *Crataegus* (ground and tip of leaves) and *Alchemilla*.

Species of genus *Sempervivum* and *Sedum* exercise antimicrobiotic activity, therefore being traditionally applied (juice obtained from its squashed leaves) by ear infections and inflammatory skin conditions (Tucakov, 1973; Redzic, 1999, 2005). Resin of fir is the basic ingredient for the preparation of special balms for treatment of hard-healing wounds.

Usage of Wild Edible Plants for Other Purposes

During chronic food and medicine shortages in this area, people did not have access to tobacco as well, especially in the northern part of Bosnia where tobacco does not grow. As a substitute for real tobacco, people used to smoke a mixture of dried leaves of *Tussilago farfara* and walnut *Juglans regia*. This mixture was consumed by people of the surrounding Sarajevo, during its siege (1992–95). Whereby in some remote regions of the country, dried leaves of *Prunus spinosa* were used and *Datura stramonium* (noted were even cases of poisoning). Even today in some remote places, children are poisoned by smoking leaves of burdock *Arctium lappa* and plants of worm *Clematis vitalba*.

Dried flowering branches of *Hysopus officinalis*, *Satureja subspicata*, *Thymus sp.*, and the root of *Inula helenium* are being burned during religious ceremonies.

ACKNOWLEDGMENTS

The author owes gratitude to the people who have supported him during the difficult field investigation, especially to Mr. Sedik Velic, technician of the Department of Pharmaceutical Botany of the Faculty of Science University of Sarajevo. The author is also thankfull to Mr. Mirnes Zukanovic, Faculty of Political Sciences, University of Sarajevo and to English language expert Ms. Sabina Trakic for efforts made in the translation of this article into English, and the entire revision of its original text written in the Bosnian language.

Herewith the author would like to express my deepest gratitude to the great man and scientist, distinguished Professor Rob Verpoort for showing enormous understanding and providing me with the support by his highly useful suggestions, both as a friend and colleague, in order to give an adequate final form to this article, which would be acceptable to the international, scientific audience.
